

# HMAC

- ❑ Can compute a MAC of the message  $M$  with key  $K$  using a “hashed MAC” or **HMAC**
- ❑ HMAC is a *keyed* hash
  - Why would we need a key?
- ❑ How to compute HMAC?
- ❑ Two obvious choices:  $h(K,M)$  and  $h(M,K)$
- ❑ Which is better?

# HMAC

- ❑ Should we compute HMAC as  $h(K,M)$  ?
- ❑ Hashes computed in blocks
  - $h(B_1, B_2) = F(F(A, B_1), B_2)$  for some  $F$  and constant  $A$
  - Then  $h(B_1, B_2) = F(h(B_1), B_2)$
- ❑ Let  $M' = (M, X)$ 
  - Then  $h(K, M') = F(h(K, M), X)$
  - Attacker can compute HMAC of  $M'$  without  $K$
- ❑ Is  $h(M, K)$  better?
  - Yes, but... if  $h(M') = h(M)$  then we might have  $h(M, K) = F(h(M), K) = F(h(M'), K) = h(M', K)$

# Correct Way to HMAC

- ❑ Let  $B$  be the block length of hash, in bytes
  - $B = 64$  for MD5 and SHA-1 and Tiger
- ❑  $\text{ipad} = 0x36$  repeated  $B$  times
- ❑  $\text{opad} = 0x5C$  repeated  $B$  times
- ❑ Then

$$\text{HMAC}(M, K) = h(K \oplus \text{opad}, h(K \oplus \text{ipad}, M))$$

# Hash Uses

- ❑ Authentication (HMAC)
- ❑ Message integrity (HMAC)
- ❑ Message fingerprint
- ❑ Data corruption detection
- ❑ Digital signature efficiency
- ❑ Anything you can do with symmetric crypto
- ❑ Also, many, many clever/surprising uses...

# Online Bids

- ❑ Suppose Alice, Bob and Charlie are bidders
- ❑ Alice plans to bid A, Bob B and Charlie C
- ❑ They don't trust that bids will stay secret
- ❑ A possible solution?
  - Alice, Bob, Charlie submit **hashes**  $h(A)$ ,  $h(B)$ ,  $h(C)$
  - All hashes received and posted online
  - Then bids A, B, and C submitted and revealed
- ❑ Hashes don't reveal bids (one way)
- ❑ Can't change bid after hash sent (collision)

# Hashing for Spam Reduction

- ❑ Spam reduction
- ❑ Before accept email, want proof that sender had to “work” to create email
  - Here, “work” == CPU cycles
- ❑ Goal is to limit the amount of email that can be sent
  - This approach will not eliminate spam
  - Instead, make spam more costly to send

# Spam Reduction

- Let  $M$  = complete email message  
 $R$  = value to be determined  
 $T$  = current time
- Sender must determine  $R$  so that  
 $h(M, R, T) = (00\dots 0, X)$ , that is,  
initial  $N$  bits of hash value are **all zero**
- Sender then sends  $(M, R, T)$
- Recipient accepts email, provided that...  
 $h(M, R, T)$  begins with  $N$  zeros

# Spam Reduction

- ❑ Sender:  $h(M,R,T)$  begins with  $N$  zeros
- ❑ Recipient: verify that  $h(M,R,T)$  begins with  $N$  zeros
- ❑ **Work for sender:** on average  $2^N$  hashes
- ❑ **Work for recipient:** always 1 hash
- ❑ Sender's work increases exponentially in  $N$
- ❑ Small work for recipient, regardless of  $N$
- ❑ Choose  $N$  so that...
  - Work acceptable for normal amounts of email
  - Work is too high for spammers

# Secret Sharing

# Shamir's Secret Sharing

2 out of 2

- Two points determine a line
- Give  $(X_0, Y_0)$  to Alice
- Give  $(X_1, Y_1)$  to Bob
- Then Alice and Bob must cooperate to find secret  $S$
- Easy to make "m out of n" scheme for any  $m \leq n$

# Shamir's Secret Sharing

- Give  $(X_0, Y_0)$  to Alice
- Give  $(X_1, Y_1)$  to Bob
- Give  $(X_2, Y_2)$  to Charlie
- Then any *two* can cooperate to find secret S
- No *one* can determine S
- A "2 out of 3" scheme

# Shamir's Secret Sharing

- Give  $(X_0, Y_0)$  to Alice
- Give  $(X_1, Y_1)$  to Bob
- Give  $(X_2, Y_2)$  to Charlie
- 3 pts determine parabola
- Alice, Bob, **and** Charlie must cooperate to find S
- A "3 out of 3" scheme
- What about "3 out of 4"?

# Secret Sharing Use?

- ❑ **Key escrow** — suppose it's required that your key be stored somewhere
- ❑ But you don't trust FBI to store your keys
- ❑ We can use secret sharing
  - Say, three different government agencies
  - Two must cooperate to recover the key

# Secret Sharing Example

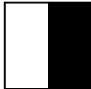

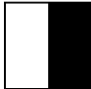

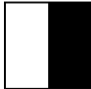

- ❑ Your symmetric key is  $K$
- ❑ Point  $(X_0, Y_0)$  to FBI
- ❑ Point  $(X_1, Y_1)$  to DoJ
- ❑ Point  $(X_2, Y_2)$  to DoC
- ❑ To recover your key  $K$ , two of the three agencies must cooperate
- ❑ No one agency can get  $K$

# Visual Cryptography

- ❑ Another form of secret sharing...
- ❑ Alice and Bob "share" an image
- ❑ Both must cooperate to reveal the image
- ❑ Nobody can learn anything about image from Alice's share or Bob's share
  - That is, both shares are required
- ❑ Is this possible?

# Visual Cryptography

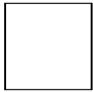

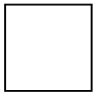

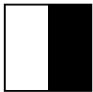

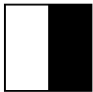

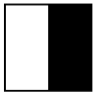

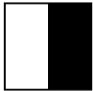

- ❑ How to “share” a pixel?
- ❑ Suppose image is black and white
- ❑ Then each pixel is either black or white
- ❑ We split pixels as shown

	Pixel	Share 1	Share 2	Overlay
a.				
b.				
c.				
d.				

# Sharing Black & White Image

- If pixel is white, randomly choose a or b for Alice's/Bob's shares
- If pixel is black, randomly choose c or d
- No information in one "share"

	Pixel	Share 1	Share 2	Overlay
a.				
b.				
c.				
d.				

# Visual Crypto Example

□ Alice's share

□ Bob's share

□ Overlaid shares

# Random Numbers in Cryptography

# Random Numbers

- ❑ Random numbers used to generate **keys**
  - Symmetric keys
  - RSA: Prime numbers
  - Diffie Hellman: secret values
- ❑ Random numbers also used in simulations, statistics, etc.
  - "statistically" random numbers

# Random Numbers

- ❑ *Cryptographic random* numbers must be statistically random and **unpredictable**
- ❑ Suppose server generates symmetric keys
  - Alice:  $K_A$
  - Bob:  $K_B$
  - Charlie:  $K_C$
  - Dave:  $K_D$
- ❑ Alice, Bob, and Charlie don't like Dave...
- ❑ Alice, Bob, and Charlie, working together, must not be able to determine  $K_D$

# Non-random Random Numbers

- ❑ Online version of Texas Hold 'em Poker
  - ASF Software, Inc.

Player's hand

Community cards in center of the table

- ❑ Random numbers used to shuffle the deck
- ❑ Program did not produce a random shuffle
- ❑ A serious problem, or not?

# Card Shuffle

- ❑ There are  $52! > 2^{225}$  possible shuffles
- ❑ The poker program used “random” 32-bit integer to determine the shuffle
  - So, only  $2^{32}$  distinct shuffles could occur
- ❑ Code used Pascal pseudo-random number generator (PRNG): Randomize()
- ❑ Seed value for PRNG was function of number of milliseconds since midnight
- ❑ Less than  $2^{27}$  milliseconds in a day
  - So, less than  $2^{27}$  possible shuffles

# Card Shuffle

- ❑ Seed based on milliseconds since midnight
- ❑ PRNG re-seeded with each shuffle
- ❑ number of shuffles could be reduced to  $2^{18}$  which can be tested in real time
- ❑ Attacker knows **every card** after the first of five rounds of betting!

# Poker Example

- ❑ Poker program is an extreme example
  - But common PRNGs are predictable
  - Only a question of how many outputs must be observed before determining the sequence
- ❑ Crypto random sequences not predictable
  - For example, keystream from RC4 cipher
  - But “seed” (or key) selection is still an issue!
- ❑ How to generate initial **random** values?
  - Keys (and, in some cases, seed values)

# What is Random?

- ❑ True “random” is hard to define
- ❑ **Entropy** is a measure of randomness
- ❑ Good sources of “true” randomness
  - Radioactive decay
  - Hardware devices ( e.g. thermal noise, photoelectric effect)
  - Lava lamp — relies on chaotic behavior

# Randomness

- ❑ Sources of randomness via software
  - Software is supposed to be deterministic
  - So, must rely on external “random” events
  - Mouse movements, keyboard dynamics, network activity, etc.
- ❑ Can get **quality** random bits by such methods
- ❑ Bottom line: “The use of pseudo-random processes to generate secret quantities can result in pseudo-security”

# Information Hiding

# Information Hiding

## ❑ Digital Watermarks

- Example: Add “invisible” info to data
- Defense against music/software piracy

## ❑ Steganography

- “Secret” communication channel
- Example: Hide data in an image file

# Watermark

- ❑ Add a “mark” to data
- ❑ Visibility (or not) of watermarks
  - Invisible — Watermark is not obvious
  - Visible — Such as TOP SECRET
- ❑ Strength (or not) of watermarks
  - Robust — Readable even if attacked
  - Fragile — Damaged if attacked

# Watermark Examples

- ❑ Add **robust invisible** mark to digital music
  - If pirated music appears on Internet, can trace it back to original source of the leak
- ❑ Add **fragile invisible** mark to audio file
  - If watermark is unreadable, recipient knows that audio has been tampered with (integrity)
- ❑ Combinations of several types are sometimes used
  - E.g., visible plus robust invisible watermarks

# Watermark Example

- ❑ Non-digital watermark: U.S. currency

- ❑ Image embedded in paper
  - Hold bill to light to see embedded info

# Steganography

- ❑ According to Herodotus (Greece 440 BC)
  - Shaved slave's head
  - Wrote message on head
  - Let hair grow back
  - Send slave to deliver message
  - Shave slave's head to expose a message warning of Persian invasion
- ❑ Historically, steganography used by military more often than cryptography

# Images and Steganography

- ❑ Images use 24 bits for color: **R****G****B**
  - 8 bits for **red**, 8 for **green**, 8 for **blue**
- ❑ For example
  - **0x7E** **0x52** **0x90** is this color
  - **0xFE** **0x52** **0x90** is this color
- ❑ While
  - **0xAB** **0x33** **0xF0** is this color
  - **0xAB** **0x33** **0xF1** is this color
- ❑ Low-order bits don't matter...

# Images and Stego

- ❑ Given an uncompressed image file...
  - For example, BMP format
- ❑ ...we can insert information into low-order RGB bits
- ❑ Since low-order RGB bits don't matter, changes will be "invisible" to human eye
  - But, computer program can "see" the bits

# Watermarking Example

- ❑ Left side: plain Alice image
- ❑ Right side: Alice with the entire *Alice in Wonderland* (pdf) "hidden" in the image

# Steganography

- ❑ Some formats (e.g., image files) are more difficult than html for **humans** to read
  - But easy for computer programs to read...
- ❑ Easy to hide info in **unimportant bits**
- ❑ Easy to damage info in unimportant bits
- ❑ To be *robust*, must use **important bits**
  - But stored info must not damage data
  - Collusion attacks are also a concern
- ❑ Robust steganography is tricky!

# Information Hiding: The Bottom Line

- ❑ Not-so-easy to hide digital information
  - “Obvious” approach is **not** robust
  - Stego/watermarking are active research topics
- ❑ If information hiding is suspected
  - Attacker may be able to make information/watermark unreadable
  - Attacker may be able to read the information, given the original document (image, audio, etc.)
